
AUTOMATED INTERPRETABILITY METRICS DO NOT DISTINGUISH TRAINED AND RANDOM TRANSFORMERS

ABSTRACT

Sparse autoencoders (SAEs) have become a central tool for extracting sparse, human-interpretable latents from transformer activations. We directly test whether the SAE quality metrics and automatic explanation pipelines now used to validate these latents distinguish trained transformers from randomly initialized transformers, including models whose parameters are sampled i.i.d. from a Gaussian. Across Pythia model scales and multiple randomization schemes, we show that SAEs trained on randomly initialized transformers often achieve auto-interpretability scores and reconstruction metrics that closely match those obtained from trained models. This finding establishes a clear limitation of aggregate SAE evaluations: high auto-interpretability scores do not, on their own, demonstrate recovery of learned, computationally relevant features. We therefore position randomized baselines as a necessary standard for SAE evaluation and argue that mechanistic interpretability needs metrics that directly test the abstractness and learned computational role of recovered features.

1 INTRODUCTION

Sparse autoencoders (SAEs) are now a leading method in mechanistic interpretability for disentangling neural representations into sparse, human-interpretable features learned from network activations (Elhage et al., 2022; Sharkey et al., 2022; Cunningham et al., 2023; Bricken et al., 2023). The method trains an autoencoder with a high-dimensional hidden layer to reconstruct activations under a sparsity constraint (Gao et al., 2024; Templeton et al., 2024; Lieberum et al., 2024), with the intended payoff of exposing the concepts or ‘features’ represented by the network (Park et al., 2023; Wattenberg and Viégas, 2024). Because SAE design increasingly depends on automated evaluation, quantitative metrics—especially auto-interpretability scores that compare generated explanations with activation patterns—now play a decisive role in judging whether an SAE has succeeded (Bills et al., 2023; Paulo et al., 2024; Karvonen et al., 2024a).

A robust interpretability method must separate features produced by training from artifacts induced by the data distribution or model architecture. The natural sanity check is therefore direct: compare the method’s output on a trained model with its output on a strong null model, such as a model with randomly initialized weights (Adebayo et al., 2020). We apply this check to SAEs and show that several common quantitative metrics fail to make this distinction reliably. Most notably, SAEs trained on transformers with random parameters can produce latents whose auto-interpretability scores (Bills et al., 2023; Paulo et al., 2024) are strikingly close to those from the corresponding fully trained model.

This result sharply constrains what aggregate SAE metrics can establish. High auto-interpretability scores alone do not demonstrate that an SAE has identified complex computations learned during training. Instead, these scores can reflect simpler statistical properties of the training data (Dooms and Wilhelm, 2024) or architectural inductive biases that are present before training begins. A randomly initialized network can still implement a basic computation, such as preserving or amplifying sparse structure in its inputs (Section 4). From that perspective, SAEs may be accurately interpreting this simple, inherent computation rather than recovering the mechanisms responsible for trained-model capabilities.

Although some SAE features from trained models clearly arise from learned computation, the commonly used aggregate metrics are not strong enough to certify that a given SAE has recovered

those richer features. This limitation has immediate consequences for mechanistic interpretability research. It makes rigorous null-model validation essential, and it demands evaluation methods that explicitly separate artifacts from genuinely learned computations.

Finally, we identify two concrete mechanisms that can explain why these patterns arise. At a high level, either (1) the input data already exhibits superposition and randomly initialized neural networks largely preserve it, or (2) randomly initialized neural networks amplify or even introduce superposed structure into the input data (e.g., given dense input generated i.i.d. from a Gaussian). Section 4 provides toy models showing that both mechanisms are plausible, while leaving the precise contribution of each mechanism in large transformers to future work.

2 RELATED WORK

Sparse dictionary learning The phenomenon now called ‘superposition’ in neural networks has a clear precedent in computational neuroscience. Olshausen and Field (1996; 1997) showed that receptive fields of simple cells in the mammalian visual cortex can be explained by sparse coding: a relatively large set of signals is represented by simultaneously activating only a small number of elements. Coding theory therefore gives a principled lens for extracting the ‘underlying signals’ responsible for neural network activations (Marshall and Kirchner, 2024).

Sparse dictionary learning (SDL) formalizes this objective by approximating input vectors as linear combinations of a small number of learned basis vectors. The learned basis is typically overcomplete, with more dimensions than the inputs it represents. SDL algorithms include Independent Component Analysis (ICA), which finds a linear representation whose components are maximally statistically independent (Bell and Sejnowski, 1995; Hyvärinen and Oja, 2000). Sparse autoencoders (SAEs) instantiate the same idea with a simple neural architecture (Lee et al., 2006; Ng, 2011; Makhzani and Frey, 2014). In the standard setting, a single-hidden-layer autoencoder that is many times wider than the input activations is trained with an objective that enforces or incentivizes hidden-layer sparsity. We refer to a single hidden-layer neuron, or dimension, as a **latent**.

Mechanistic interpretability Mechanistic interpretability increasingly treats language-model ‘features’ or concepts as low-dimensional subspaces of internal activations (Park et al., 2023; Wattenberg and Viégas, 2024; Engels et al., 2024). If this sparse or ‘superposed’ structure is real, then targeted interventions on activations should express, suppress, or replace concepts and thereby influence model behavior (Meng et al., 2022; Zhang and Nanda, 2023; Heimersheim and Nanda, 2024; Makelov, 2024; O’Brien et al., 2024).

SAEs are the dominant practical approach for discovering such features: one typically trains an autoencoder to reconstruct activations from a single layer, such as the transformer residual stream (Sharkey et al., 2022; Cunningham et al., 2023; Bricken et al., 2023). Recent SAE variants primarily differ in the activation function or sparsity mechanism applied after the linear encoder (Makhzani and Frey, 2014; Gao et al., 2024; Rajamanoharan et al., 2024b; Lieberum et al., 2024). Other work changes the training objective (Braun et al., 2024; Farnik et al., 2025) or extends the approach across multiple layers simultaneously (Yun et al., 2021; Lawson et al., 2024; Lindsey et al., 2024).

Beyond reconstruction error and preservation of the underlying model’s performance, SAE evaluations now ask whether latents capture specific concepts (Gurnee et al., 2023; Gao et al., 2024), encode factual knowledge (Huang et al., 2024; Chaudhary and Geiger, 2024), or support targeted ‘unlearning’ of concepts (Karvonen et al., 2024b).

Automatic neuron description SAEs routinely learn tens of thousands of latents, making exhaustive manual description impractical. Yun et al. (2021) identify the tokens that maximally activate a dictionary element and inspect the resulting activation patterns by hand. Modern SAE work instead collects latent activation patterns over a text dataset and prompts a large language model to explain them (e.g. Bills et al., 2023; Foote et al., 2023). These automatic description methods are now widely used in SAE research (e.g. Cunningham et al., 2023; Bricken et al., 2023; Gao et al., 2024; Templeton et al., 2024; Lieberum et al., 2024).

Bills et al. (2023) generate explanations for language-model neuron activation patterns, simulate activations from those explanations, and score explanations by comparing simulated and observed

activations. This procedure defines the auto-interpretability paradigm used throughout this paper. Paulo et al. (2024) make the paradigm cheaper by introducing classification-based fidelity measures and an open-source pipeline for computing them. Choi et al. (2024) further strengthen automatic description by using best-of- k sampling to generate multiple explanations from different subsets of maximally activating examples. They then fine-tune Llama-3.1-8B-Instruct on the top-scoring explanations to obtain inexpensive ‘explainer’ and ‘simulator’ models.

Polysemanticity Lecomte et al. (2024) observe that individual neurons can become polysemantic incidentally. A polysemantic neuron, or basis dimension, represents multiple interpretable concepts (Elhage et al., 2022; Scherlis et al., 2023); individual neurons in a randomly initialized network can therefore be polysemantic without revealing much about learned computation. Our focus is different: we study *superposition* (Elhage et al., 2022; Chan, 2024), a layer-level representational property rather than a property of a single neuron. Superposition allows a whole layer to represent more sparse features than it has dense neurons by exploiting the fact that only a few concepts are active at a time, i.e., at a given token position.

Training only the embeddings Zhong and Andreas (2024) show that transformers can acquire surprising algorithmic capabilities when only their embeddings are trained. That result demonstrates that a randomly initialized transformer can be strongly shaped by a small trained parameter subset. Our setting deliberately isolates a different question: in the ‘Step-0’ and ‘Re-randomized incl. embeddings’ variants, we randomize *all* parameters, including embeddings, while also evaluating SAEs. The ‘Re-randomized excl. embeddings’ variant retains pre-trained embeddings, but we freeze those embeddings and randomize the remaining weights rather than training embeddings against fixed random weights (Section 3).

Random transformers for board games Karvonen et al. (2024c) found that SAEs extracted meaningful chess structure much more effectively from pre-trained transformers than from random-weight transformers. This contrast is important, but board-game data differs sharply from language data. Language plausibly contains sparse structure that aligns with conceptual meaning: a concept such as ‘serendipitous’ appears only rarely. Board games need not have the same property, since a strategically useful concept such as a knight fork need not occur sparsely across games.

Random one-layer transformers Bricken et al. (2023) found that auto-interpretability scores clearly discriminated between random and trained one-layer transformers. Our results refine this picture: randomized models score relatively low for smaller models (e.g., Pythia-70m), but the trained-randomized gap narrows substantially at larger scale (e.g., Pythia-6.9b).

3 RESULTS

We trained per-layer SAEs on residual-stream activation vectors from Pythia transformer language models ranging from 70M to 7B parameters (Biderman et al., 2023). The comparison deliberately spans trained models, randomized null models, and a negative control:

- **Trained:** The standard trained model.
- **Re-randomized incl. embeddings:** Every model parameter, including embeddings, is re-initialized by sampling Gaussian noise whose mean and variance match the corresponding weight matrix in the trained model.
- **Re-randomized excl. embeddings:** The same re-randomization procedure is applied, but embedding and unembedding matrices are kept fixed to their trained values.
- **Step-0:** For Pythia models, the step0 revisions provide the original model weights at initialization, before any learning (Biderman et al., 2023).
- **Control:** The trained model is used, but input token embeddings are replaced at inference time with i.i.d. standard Gaussian noise for each token occurrence, so a token has no consistent embedding vector. This variant should drive auto-interpretability to chance.

The primary experiments train SAEs on 100M RedPajama tokens (Weber et al., 2024) with a 10M-token activation buffer; Appendix C shows that the same qualitative conclusions hold for a subset of

Figure 1: ‘Fuzzing’ ROC curve vs. layer for Pythia-6.9b (100 latents sampled per SAE). The trained model (gray line) and randomized variants (colored) overlap, whereas the control (black) is near chance (dotted). This suggests aggregate AUROC alone is insufficient to attribute latents to learned computation. See Figure 2 for other metrics/model sizes and Appendix E for multiple random seeds.

SAEs trained on one billion tokens. For models below 410M parameters, we trained an SAE at every layer; for Pythia-1b, we trained SAEs at every second layer, and for Pythia-6.9b, we trained SAEs at every fourth layer.

Unless otherwise stated, we use k -sparse autoencoders (TopK SAEs; Makhzani and Frey 2014; Gao et al. 2024) with expansion factor $R = 64$ and sparsity $k = 32$. A hyperparameter sweep on Pythia-160m, spanning expansion factors that are powers of 2 from 16 to 128 and sparsities of 16 and 32, confirms that the central result is not an artifact of this default choice (Figure 18). The training implementation builds on Belrose et al. (2025), and the evaluations build on Caden et al. (2025) and Karvonen et al. (2024a).

Auto-interpretability Auto-interpretability converts a feature explanation into a testable prediction: if the explanation identifies a concept, a classifier should determine whether that concept appears in text inputs. This classifier can then be evaluated with standard metrics such as the area under the receiver operating characteristic (ROC) curve (AUROC). Paulo et al. (2024) introduced ‘fuzzing’ and ‘detection’ classification tasks for evaluating feature explanations. In ‘fuzzing’ scoring, positive and negative token examples (i.e., with non-zero and zero activation values, respectively) for a latent are delimited with special characters, and a language model must identify which examples have been correctly delimited given the latent explanation. In ‘detection’ scoring, a language model must identify which examples contain activating tokens for each feature. Bills et al. (2023) originally proposed ‘simulation’ scoring, which evaluates the correlation between predicted and observed activations, but this method is substantially more expensive to compute.

Except where noted, we use ‘fuzzing’ scores as our primary auto-interpretability measure because they have been shown to correlate with simulation scoring (Paulo et al., 2024). Appendix B reports the corresponding AUROC curves for ‘detection’ scoring. For each trained SAE, defined by the underlying model, variant, and layer, we randomly sampled 100 features and computed auto-interpretability scores. Our implementation follows Paulo et al. (2024). We use Meta-Llama-3.1-70B-Instruct-AWQ-INT4 to generate explanations and make predictions, giving us a larger model than the 8B models used by Choi et al. (2024) while remaining open-source, unlike Bills et al. 2023.

The auto-interpretability scores are far closer between trained and randomized models than between either group and the control (Figures 1 and 2). This alignment in ROC scores demonstrates that

‘fuzzing’ auto-interpretability alone, applied to SAE latent explanations, does not reliably distinguish trained transformers from randomized ones.

Evaluation We evaluated standard SAE metrics alongside auto-interpretability AUROC for Pythia models from 70M to 6.9B parameters. Across these metrics, the randomly initialized and re-randomized models (Figure 2; blue, green, orange lines) consistently resemble the trained model (Figure 2; gray lines) more than the control (Figure 2; black lines).

The reconstruction-based metrics sharpen this pattern: cosine similarity between original activations and SAE reconstructions, as well as explained variance, are often much lower for the random control than for the other variants, and its reconstruction errors increase across layers while the remaining variants tend to decrease. One plausible explanation is that a Gaussian is the highest-entropy distribution with fixed mean and variance (Jaynes, 2003); in this sense, Gaussian vectors are minimally structured and therefore especially difficult for SAEs to reconstruct. As Gaussian-distributed activations propagate through successive layers, they may become less Gaussian and more ‘sparse’, making them easier to reconstruct (Section 4).

The randomized variants (blue and orange lines) are also closer to the trained model than the initialization checkpoint (green line), particularly in the L^1 norm values for larger models. This pattern is consistent with parameter norms changing substantially during training, while our re-randomization procedure deliberately preserves the trained model’s per-matrix parameter scale. Layerwise parameter scale may be important for controlling activation growth through the residual stream (Liu et al., 2020). The AUROC plots further show that, for every variant except the control, AUROC increases with model size. A plausible interpretation is that features become more specific as SAE size increases: in smaller SAEs, each latent must explain more of the input, whereas larger SAEs can allocate latents to narrower patterns that are easier for the classifier to identify.

Figure 2 (row five) reports the cross-entropy (CE) loss score, or loss recovered, as a function of layer. This score is the increase in loss when original model activations are replaced by SAE reconstructions divided by the increase when those activations are replaced by zeros (‘ablated’). For the ‘trained’ variant, our SAEs match the performance of comparable SAEs in the literature (e.g., Kissane et al., 2024; Rajamanoharan et al., 2024a; Mudide et al., 2024). The CE loss score is meaningful only for the trained variant: for randomized variants, the model loss is already very poor, regardless of whether the original or reconstructed activations are used.

Latent explanation complexity The similarity of aggregate metrics does not imply qualitative equivalence between the learned latents. We expected SAEs trained on randomized variants to recover relatively simple features tied to input-text statistics, rather than the more complex and abstract features found in trained transformers (Templeton et al., 2024). For qualitative examples, we provide a random sample of features and the corresponding maximally activating dataset examples for each variant of Pythia-6.9b in Appendix J, and more detailed information in Appendix L.

A substantial fraction of SAE latents activate only on a single token or a small set of distinct tokens within a text dataset (e.g., Lin and Bloom, 2024; Dooms and Wilhelm, 2024). This observation gives a simple operational measure of latent complexity: whether the latent activates on one token ID or across many distinct IDs. We quantify this using the entropy of the observed distribution of latent activations over tokens; higher entropy means that activations are more spread out and less token-specific. We define the distribution as the total latent activation per token across the maximally activating examples used to generate auto-interpretability explanations. We show the relationship between entropy and ‘fuzzing’ AUROC score for individual latents in Appendix H.

The last row of Figure 2 reports the entropy of the observed latent-activation distributions over token IDs. The negative control has consistently high entropy, as expected: the embedding for a given token ID is sampled i.i.d. from a Gaussian on each occurrence, so the token has no stable embedding vector (Section 3). In the trained variant, entropy increases across layers, meaning that deeper-layer maximally activating examples are less concentrated on a single token. This trend matches the expectation that later layers encode more abstract features that are less tied to token embeddings. By contrast, randomized models tend to have lower entropy than either the trained or control variants, indicating latents that activate specifically on one or a few token IDs.

Figure 2: Comparison of sparse autoencoder performance across Pythia models (70M to 6.9B parameters). The different SAE variants show remarkably similar trends across model scales, with larger models exhibiting more consistent behavior across layers. All variants save for control achieve comparable performance despite fundamentally different initialization approaches.

Figure 3: An example of the effect of a randomly initialized neural network on superposed input data. We take 10K samples of $n_s = 3$ sparse input features from a Lomax distribution with shape $\alpha = 1$ and scale $\lambda = 1$ and project these to $n_d = 2$ dense input features by an i.i.d. standard normal matrix. Then, we pass the dense outputs to a two-layer MLP with ReLU activation and hidden size of $4n_d$ and recover $n_s = 3$ sparse outputs by the inverse of the previously generated projection matrix.

Together, these results show that standard SAE quality and auto-interpretability metrics miss an important dimension of SAE features: their ‘abstractness’. Token-distribution entropy is only a proxy for ‘abstractness’, but it exposes a decisive contrast hidden by aggregate auto-interpretability scores: randomized variants can learn simple, single-token features that score well. Unlike the trained variant, however, their features do not become progressively more complex with depth.

4 A TOY MODEL OF SUPERPOSITION IN RANDOM NETWORKS

Section 1 identified two mechanisms that can explain why randomized transformers yield sparse and interpretable SAE latents: the input data may already exhibit superposition that neural networks preserve, and neural networks may amplify or introduce superposition in their inputs. This section tests both mechanisms with toy models. The evidence supports the plausibility of both mechanisms, while the question of which dominates in randomized transformers remains open.

4.1 MATRIX MULTIPLICATIONS PRESERVE SUPERPOSITION

First, a simplified linear model shows that multiplication by a weight matrix W preserves superposition. Imagine that we generate superposed input data x by first generating n_s i.i.d. ‘sparse’ features z from a heavy-tailed Lomax distribution $z \sim \text{Lomax}(\alpha, \lambda)$. We can project the higher-dimensional, sparse z down to lower-dimensional, dense x with a matrix D , then add Gaussian noise with a small variance Σ , $x \sim \mathcal{N}(x; Dz, \Sigma)$. Importantly, if we multiply x by some matrix W , then $x' = Wx$ is also superposed: it is generated by the same model as x , except with different noise covariances and mappings from z to x , namely $x' \sim \mathcal{N}(z; WDz, W\Sigma W^T)$.

The same intuition extends naturally to nonlinear networks, as shown by passing the dense activations through a simple feed-forward network (MLP). Figure 3 gives a concrete example: $n_s = 3$ sparse features are projected to $n_d = 2$ dense features, and the MLP outputs still appear superposed despite the nonlinearity. The visualization also indicates amplification, not merely preservation: compared with the inputs (Figures 3a and 3b), the outputs (Figures 3d and 3c) contain fewer points between the ‘arms’.

4.2 DO RANDOM NNS PRESERVE OR AMPLIFY SUPERPOSITION?

We tested this amplification hypothesis using toy data generated with the procedure of Sharkey et al. (2022): ground-truth features are sampled on a hypersphere, and correlated feature coefficients are generated so that only a small number are active (Appendix I.1). We passed these inputs through a two-layer MLP at initialization and trained separate SAEs on the inputs and outputs. As a control, we used Gaussian inputs with the same mean and standard deviation as the superposed toy data. All SAEs used a standard L^1 sparsity penalty (Appendix I.2).

Figure 4: The mean max cosine similarity (MMCS) between the features learned by a standard SAE (decoder weight vectors) and the data-generating features against the L^1 penalty coefficient in the training loss, following Sharkey et al. (2022). There is a ‘Goldilocks zone’ where SAEs near-perfectly recover the data-generating features, given enough latents to represent them.

(a) Toy datasets following Sharkey et al. (2022). (b) 300-dim. GloVe vectors (Pennington et al., 2014).

Figure 5: Pareto frontiers of the explained variance against the L^1 norm divided by the square root of the L^2 norm (sparsity) for datasets perhaps exhibiting superposition, Gaussian controls with the same mean and variance, and the corresponding outputs when these are passed to a randomly initialized two-layer MLP (Section 4.2). Each point denotes a choice of L^1 penalty coefficient.

Following Sharkey et al. (2022), we first verify that SAEs recover the ground-truth features that generated the inputs (Figure 4). We measure mean max cosine similarity (MMCS): for each data-generating feature, we compute its maximum cosine similarity with the SAE-learned features (the decoder weight vectors) and average over data-generating features. MMCS applies only to the MLP inputs, where the data-generating features are known, so the MLP outputs require a different analysis. We therefore use the ability of SAEs to obtain low reconstruction error at high sparsity as a proxy for the extent to which the training data exhibits superposition. Concretely, we vary the L^1 penalty coefficient to trace Pareto frontiers of explained variance against sparsity measures (Figure 5a).

As expected, SAEs achieve much greater sparsity at a fixed level of explained variance for superposed inputs than for the Gaussian control (Figure 5a; orange and blue-green). After the randomly initialized MLP, however, the gap between superposed outputs and Gaussian outputs becomes much smaller: the former have only slightly greater sparsity at the same explained variance. This result supports the claim that randomly initialized MLPs can produce relatively sparse outputs even when the input distribution is not explicitly superposed. We consider other sparsity measures and hyperparameters in Appendix I.

4.3 DO TOKEN EMBEDDINGS EXHIBIT SUPERPOSITION?

If randomly initialized neural networks preserve or amplify superposition, then the results in Section 3 may depend on how strongly transformer inputs already exhibit superposition. We test this possibility by applying the procedure from Section 4.2 to language data. Specifically, we train SAEs on pre-trained GloVe word vectors, Pythia embedding matrices, the outputs produced by passing these inputs through a randomly initialized two-layer MLP, and Gaussian controls. The setup matches Section 4.2, except that the number of data points is fixed by the number of word embeddings or tokens, and we use a single random seed.

The gap between the Pareto frontiers of GloVe word vectors and their Gaussian controls (Figure 5b) is smaller than the corresponding gap for the toy superposed datasets in Section 4.2 (Figure 5a). More importantly, the Pareto frontiers for both inputs improve after passage through a randomly initialized two-layer MLP, reinforcing the conclusion that random NNs can ‘sparsify’ their inputs, i.e., increase apparent superposition.

5 LIMITATIONS

This work demonstrates that auto-interpretability measures can assign apparently meaningful explanations to SAEs trained on randomly initialized models, even though those models are unlikely to contain the learned computations of interest. Because no single study can cover all datasets and model architectures, we focus on the Pythia family, a standard choice in mechanistic interpretability research (e.g., Paulo and Belrose, 2025; Ghilardi et al., 2025; Mueller, 2024), and on RedPajama-V2 as representative pre-training data for language models and SAEs.

We use the default explanation model in the EleutherAI auto-interpretability framework (Caden et al., 2025); evaluating alternative explanation models remains an important way to test how much the aggregate behavior depends on the explainer. Crucially, we do not claim that SAEs fail to capture information in trained Transformers beyond what is present in randomly initialized transformers. Our claim is narrower and stronger: aggregate auto-interpretability measures do not, by themselves, establish that the underlying features are computationally interesting or learned.

6 CONCLUSION

We applied sparse autoencoders to trained and randomly initialized transformers and evaluated them with common quantitative SAE metrics. The central empirical result is clear: under the conditions studied here, aggregate metrics—especially auto-interpretability scores—can closely match across trained and randomized settings. At the same time, features from trained transformers are qualitatively more complex and abstract, particularly in later layers, and the aggregate metrics often fail to register this difference.

This result does not show that SAEs trained on real models lack meaningful computational features. It shows that current evaluation methods are not sufficient to certify those features. High aggregate auto-interpretability scores are not proof of complex learned computation: they can instead reflect simpler structure in the data or architecture that random weights preserve. Our token-distribution entropy analysis, while preliminary, provides a proof of concept for a stronger evaluation direction by revealing differences in feature ‘abstractness’ that aggregate auto-interpretability scores miss. Future SAE evaluation should therefore quantify the computational significance and abstraction level of discovered features, not merely their explainability under current automatic pipelines. The practical implication is decisive: interpretability techniques should be benchmarked against strong, appropriately constructed null models such as the randomly initialized transformers used here. Without such baselines, discovered features cannot be confidently attributed to learning.

A BROADER IMPACT

This work evaluates a method that is already central to mechanistic interpretability of LLMs and provides direct evidence that some assumptions about sparse autoencoder evaluation are too weak. By showing that SAEs can produce similar aggregate auto-interpretability scores for random and trained transformers, our findings clarify that these evaluation methods do not necessarily measure learned computation.

A clearer account of SAE quality metrics should make the search for stronger SAE-like methods more focused and should ultimately support more reliable interpretability and risk mitigation. Because this paper is an empirical evaluation of an existing method, and because it highlights limits rather than expanding model capabilities, we judge the risk of negative social impact to be minimal.

B AUTO-INTERPRETABILITY ROC CURVES

Figures 6, 8, and 12 extend the main finding by showing close ‘fuzzing’ AUROC agreement between trained and randomized SAEs for the 70M, 160M, and 1B models. Figures 7, 9, and 13 show that the same qualitative pattern holds for ‘detection’ AUROC.

B.1 PYTHIA 70M

Figure 6: ROC curves for ‘fuzzing’ auto-interpretability for Pythia-70m over 100 SAE latents. The SAE variants show similar performance, and scores degrade with increasing layer index.

Figure 7: ROC curves for ‘detection’ auto-interpretability for Pythia-70m over 100 SAE latents. The SAE variants again show similar performance, with scores declining across layers.

B.2 PYTHIA 160M

Figure 8: ROC curves for ‘fuzzing’ auto-interpretability for Pythia-160m over 100 SAE latents. The variants remain closely aligned, while performance degrades with increasing layer index.

Figure 9: ROC curves for ‘detection’ auto-interpretability for Pythia-160m over 100 SAE latents. The variants remain closely aligned, while performance degrades with increasing layer index.

B.3 PYTHIA 410M

Figure 10: ROC curves for ‘fuzzing’ auto-interpretability for Pythia-410m over 100 SAE latents. The variants show similar performance and degrade with layer index; these scores fail to distinguish trained from randomized models.

Figure 11: ROC curves for ‘detection’ auto-interpretability for Pythia-410m over 100 SAE latents. The variants show similar performance and degrade with layer index.

B.4 PYTHIA-1B

Figure 12: ROC curves for ‘fuzzing’ auto-interpretability for Pythia-1b over 100 SAE latents. The variants remain similar, and this model does not show the same overall degradation in quality.

Figure 13: ROC curves for ‘detection’ auto-interpretability for Pythia-1b over 100 SAE latents. The variants remain similar, and this model does not show the same overall degradation in quality.

B.5 PYTHIA 6.9B

Figure 14: ROC curves for ‘detection’ auto-interpretability for Pythia-6.9b over 100 SAE latents. The trained and randomized variants again exhibit similar performance.

C EFFECT OF INCREASED TRAINING DATA

Our primary experiments train SAEs on 100M tokens (Section 3). To rule out insufficient SAE training data as the explanation for the observed similarity between trained and randomized variants, we repeat a subset of experiments with SAEs trained on 1B RedPajama tokens (Figure 15).

Figure 15: Evaluation metrics for SAEs trained with one billion tokens on Pythia-70m and Pythia-410m. These columns correspond to the 100M-token results in Figure 2 and preserve the same qualitative behavior.

D EFFECT OF DECREASED TRAINING DATA FOR PYTHIA-1B

Figure 16: Evaluation metrics for SAEs trained with 1M and 1B tokens on Pythia-1b. The 1M-token SAEs are under-trained, as shown by substantially lower explained variance and CE loss score. Average auto-interpretability is slightly lower in the earliest layers and declines sharply with layer index, while auto-interpretability and token-distribution entropy follow the same layerwise trends as the other SAEs.

E UNCERTAINTY PLOTS FOR PYTHIA-70M

We quantify uncertainty in the Pythia-70m evaluation metrics using five random seeds.

Figure 17: Uncertainty in Pythia-70m metrics computed over five random seeds.

F EFFECT OF SAE HYPERPARAMETERS FOR PYTHIA-160M

Figure 18: Robustness of SAE performance to hyperparameter selection. Standard evaluation metrics remain stable across expansion factors R from 16 to 128 and sparsities k from 16 to 32, with initialization strategies preserving their relative ordering. This stability supports the use of the default moderate hyperparameters ($R = 64$, $k = 32$).

G EFFECT OF SAE HYPERPARAMETERS FOR PYTHIA-1B

Figure 19: Evaluation metrics for SAEs trained on Pythia-1b with different hyperparameters, including the main results from Figure 2. Very small SAEs ($R = 2$, $k = 4$) are clearly worse under explained variance and CE loss score, yet their auto-interpretability scores remain similar to default-hyperparameter SAEs on both trained and randomised models.

H TOKEN DISTRIBUTION ENTROPY VS. AUTO-INTERPRETABILITY

Figure 20: Scatter plots of per-latent token-distribution entropy against ‘fuzzing’ AUROC (auto-interpretability score) for SAEs trained on multiple Pythia-6.9b layers. Each point is a single latent from the sample used to compute the aggregate metrics in Figures 1 and 2.

Figure 20 separates the negative control, randomized variants, and trained variant more clearly than aggregate AUROC:

- **Control:** Latents have consistently high entropy, meaning that maximally activating examples spread activation across many tokens, and low auto-interpretability, meaning that generated explanations do not adequately capture these activation patterns. The plot shows no clear correlation between the two variables.
- **Randomized:** For each randomization scheme in Section 3, entropy and auto-interpretability are negatively correlated: as a latent activates across a wider variety of tokens, its generated explanation explains the activation pattern less well.
- **Trained:** The correlation is weaker. Crucially, beyond the broad trend seen in randomized variants, the trained model contains latents with both high entropy *and* high auto-interpretability. These latents activate across multiple tokens while remaining consistent with the generated explanation.

These results directly support the claim that aggregate auto-interpretability scores obscure important differences between SAEs trained on trained and randomized models. Randomized models with stable token embeddings can produce easy-to-explain ‘single-token’ features, but only transformers trained on natural language produce the more complex semantic features reflected by high-entropy, high-auto-interpretability latents.

I A TOY MODEL OF SUPERPOSITION

Section 4 uses SAEs trained on toy data designed to exhibit superposition (Sharkey et al., 2022) and on GloVe word vectors (Pennington et al., 2014). This appendix specifies the data-generation procedure and training setup.

I.1 DATA GENERATION

We construct the ground-truth features by sampling n_s points on an n_d -dimensional hypersphere.

For each sample, we determine feature coefficients by generating $A \in \mathbb{R}^{n_s \times n_s}$ with $A_{ij} \sim \mathcal{N}(0, 1)$, defining the covariance matrix $\Sigma = AA^\top$, sampling $\vec{\alpha} \in \mathbb{R}^{n_s}$ with $\alpha_i \sim \mathcal{N}(\vec{0}, \Sigma)$, projecting α_i onto the c.d.f. of $\mathcal{N}(0, 1)$, applying the decay $\alpha_i \rightarrow \alpha_i^{\lambda_i}$ with $\lambda \in \mathbb{R}$, normalizing $\alpha_i \rightarrow m\alpha_i / n_s \sum_j \alpha_j$ with $m \in \mathbb{R}$, and performing n_s independent Bernoulli trials with $p = \alpha_i$. We then multiply the trial outcomes by n_s independent samples from the continuous uniform distribution $\mathcal{U}_{[0,1]}$.

The parameter λ controls how sharply the frequency of nonzero ground-truth feature coefficients decays with feature index i . The parameter m fixes the expected number of nonzero feature coefficients in each sample.

Following Sharkey et al. (2022), we set $n_s = 512$, $n_d = 256$, $\lambda = 0.99$, and $m = 5$. Figure 21 gives the Python implementation used for this procedure.

I.2 TRAINING

The SAEs in Section 4 use a linear encoder with a bias term, a ReLU activation function, and a linear decoder without a bias term. We initialize decoder weights orthogonally and normalize decoder weight vectors before each training step.

The training loss is the mean squared error (MSE) between input and decoded vectors plus the mean L^1 norm of encoded vectors multiplied by a coefficient, which we vary between 1×10^{-3} and 100.

For the toy data, we train for 100 epochs on 10K data points with 10 random seeds. For the word vectors, we train for 100 epochs on 400K data points with one random seed. Both experiments reserve 10% of data points as a validation set for computing evaluation metrics.

The MLPs in Section 4 have two layers, i.e., one hidden layer, and a ReLU activation function. Input and output sizes both equal n_d , and the hidden size is $4n_d$. These choices deliberately mirror the feed-forward components of transformer language models at a simplified scale.

Figure 21: Python implementation of the data-generation procedure introduced by Sharkey et al. (2022) and used in Section 4.

Figure 22: Pareto frontiers of explained variance against the L^0 norm (sparsity) for superposed toy datasets, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 23: Pareto frontiers of explained variance against the L^1 norm (sparsity) for superposed toy datasets, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 24: Pareto frontiers of explained variance against the L^1 norm over the square root of the L^2 norm (sparsity) for superposed toy datasets, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 25: Pareto frontiers of explained variance against Hoyer sparseness for superposed toy datasets, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 26: Pareto frontiers of explained variance against sparsity measures for 50-dimensional GloVe word vectors, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 27: Pareto frontiers of explained variance against sparsity measures for 100-dimensional GloVe word embeddings, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 28: Pareto frontiers of explained variance against sparsity measures for 200-dimensional GloVe word embeddings, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

Figure 29: Pareto frontiers of explained variance against sparsity measures for 300-dimensional GloVe word embeddings, matched Gaussian controls, and their outputs after passage through a randomly initialized two-layer MLP.

J EXAMPLE FEATURES FOR PYTHIA-6.9B

VARIANT: TRAINED

FEATURE 180935 (LAYER 0)

Interpretation: This feature primarily tracks the token "security" in contexts of protection, safety, and harm prevention; the less frequent "oz" activations appear to reflect measurement contexts involving ounces.

Top Examples:

1. Text: <endoftext—¿—. If for any reason you are unhappy with our service please contact us directly so we can make it right for you.Journal of Cyber Security, Vol.
Activation: 4.3750
Active tokens: Security
2. Text: <endoftext—¿— Security Practitioner. Tremendously passing CompTIA Advanced Security Practitioner (casp) cert has never been as easy as it
Activation: 4.3125
Active tokens: Security Security
3. Text: in trusted hands for your Cyber Security career or staffing needs. Call 0203 643 0248 to find out more. Technically proficient using
Activation: 4.3125
Active tokens: Security

FEATURE 93790 (LAYER 8)

Interpretation: This feature captures economic, development, and business language, especially nouns and phrases associated with growth, progress, and improvement.

Top Examples:

1. Text: training requirements. See "Workforce" section for additional information. The Economic Development Transportation Fund, commonly referred to as the "Road Fund," is an
Activation: 21.3750
Active tokens: Development
2. Text: Montréal.The Williamsburg Economic Development Authority offers a 33% matching grant up to \$7,500 for exterior improvements to existing businesses in the City of
Activation: 20.2500
Active tokens: Development Authority
3. Text: Correction: In a July 16 web story The Real Deal incorrectly stated that the Economic Development Corporation was "circumventing" laws with its restructuring. In
Activation: 20.0000
Active tokens: Development

FEATURE 128309 (LAYER 12)

Interpretation: This feature tracks punctuation and grammatical boundary markers, including hyphens, commas, ellipses, prepositions, and determiners that signal connection, contrast, clarification, or transitions between clauses and ideas.

Top Examples:

1. Text: Run it in JDK6, and it will print "[axons, bandrils, chumblies]". If you are having trouble switching from
Activation: 8.0000
Active tokens: in JD K

-
- 1782 Text: Here, we introduce the coordinate systems for three-dimensional space □□□2. The study
1783 of 3-dimensional spaces lead us to the setting for our study
1784 2. Activation: 7.8125
1785 Active tokens: □
1786 Text: .path.expanduser("~/malwarehouse/") because this server doesn't have X-Windows running.
1787 If you are looking for a simple and
1788 3. Activation: 7.7188
1789 Active tokens: . path expand user
-

1790
1791
1792 VARIANT: STEP 0

1793
1794 FEATURE 126848 (LAYER 12)

1795 **Interpretation:** This feature groups tokens denoting trainers or instructors, measurement units or
1796 marks, and abbreviations or acronyms for standards and technologies.

1797 **Top Examples:**

- 1799 Text: What are the various lessons a member can access at a tennis club? Whether you are a
1800 1. beginner or advanced player, trainers help you to choose the right gaming
1801 Activation: 13.1250
1802 Active tokens: trainers
1803 Text: report include various simulation platforms and Serious Games. The report also analyzes
1804 some major allied products such as patient simulators and task trainers. The technologies
1805 2. analyzed
1806 Activation: 13.0625
1807 Active tokens: trainers
1808 Text: a stylish spring in your step when you buy from our fantastic range of men's and women's
1809 Asics trainers. We've got numerous styles from
1810 3. Activation: 13.0000
1811 Active tokens: trainers
-

1812
1813 FEATURE 2125 (LAYER 4)

1814
1815 **Interpretation:** This feature centers on the word "papers" in document-related contexts, including
1816 academic papers, court documents, printed materials, and writing, research, or education tasks.

1817 **Top Examples:**

- 1818 Text: caustic solution . As an abrasive, alumina is coated into abrasive papers and .. Pakistan.
1819 1. Sierra leone. Taiwan. Turkey. Venezuela.
1820 Activation: 5.7188
1821 Active tokens: papers
1822 Text: that can be associated with interaction with other individuals. For everybody who is
1823 uncertain regardless of whether your papers is misstep no cost, buy inexpensive experienced
1824 2. proofreading services
1825 Activation: 5.6875
1826 Active tokens: papers
1827 Text: who RV, often traveling in groups, often alone. You just want to have all the papers like
1828 RC, licence and insurance coverage as effectively as PUC (
1829 3. Activation: 5.6562
1830 Active tokens: papers
-

1831
1832
1833 FEATURE 9944 (LAYER 16)

1834
1835 **Interpretation:** This feature activates on word fragments that often mark the beginning or ending of
proper nouns, surnames, or foreign-origin words.

1836 **Top Examples:**

1837

1838 Text: astic gestures.Home Music World News Music the artform Where Do Music Festivals Go

1839 1. Now? Where Do Music Festivals Go Now? Are you ready

1840 Activation: 10.4375

1841 Active tokens: Fest Fest

1842 Text: client streams, and encouraging existing customers to become more involved.Welcome to

1843 2. Fil Fest USA!! Do you love lumpia? Can you eat a handful of them

1844 Activation: 10.3750

1845 Active tokens: Fest

1846 Text: Powers talking about his early inspirations. In response to San Diego Comic Fest 2012!:

1847 3. Off to Comic Fest 2012. Should be interesting if nothing else!

1848 Activation: 10.3750

1849 Active tokens: Fest Fest

1850

1851

1852 VARIANT: RANDOMIZED EXCLUDING EMBEDDINGS

1853

1854 FEATURE 151030 (LAYER 28)

1855

1856 **Interpretation:** This feature broadly captures contextually salient nouns, proper nouns, and adjectives,

1857 including tokens related to locations, people, organizations, time, and abstract concepts.

1858 **Top Examples:**

1859

1860 Text: ion Patch Kills Owner, Son,”, Los Angeles Times, June 12, 1994,

1861 1. <http://articles.latimes.com/1994-06-12>

1862 Activation: 58.0000

1863 Active tokens: lat

1864 Text: hard-headed coin of the realm their look. Firstly you’ve got to inventory on incident unique

1865 2. a distinct blunt in a retailer you superlativeness be

1866 Activation: 56.5000

1867 Active tokens: lat

1868 Text: Jr’s new film Dovlatov follows the life of the now celebrated writer Sergei Dovlatov over

1869 3. six days in 1971, as he struggles

1870 Activation: 55.7500

1871 Active tokens: lat lat

1872

1873

1874 FEATURE 98924 (LAYER 12)

1875 **Interpretation:** This feature tracks size-related adjectives and nouns for objects or concepts being

1876 characterized by size.

1877

1878 **Top Examples:**

1879

1880 Text: . The area to the right is for large dogs (small dogs also welcomed) however the area to

1881 1. the left is for small dogs only. Troup 69

1882 Activation: 46.0000

1883 Active tokens: small

1884 Text: ,I would not mind, but has to pretty less expensive. Can it use any windows aplication????

1885 2. Or I am really need a cool,small

1886 Activation: 45.5000

1887 Active tokens: small

1888 Text: 3/4” – 8 1/2” rather than strictly 8 1/4”) I chose the “small” version, though I should be a

1889 3. Activation: 44.7500

Active tokens: small

1890	FEATURE 180589 (LAYER 24)
1891	
1892	Interpretation: This feature emphasizes nouns for tasks, responsibilities, or jobs, usually in professional or organizational contexts, with occasional proper nouns and morphologically marked tokens.
1893	
1894	
1895	Top Examples:
1896	
1897	Text: completing tasks or a captcha, users are awarded by GRSfractions. Why These Groestlcoin

K COMPUTE DETAILS

All experiments ran on a single NVIDIA A100 80GB GPU in a private cluster. Table 1 reports the approximate duration of the final experiments for each model size and transformer variant. We estimate that preliminary and failed experiments required approximately the same total compute as the final experiments.

Model	Variants	Approx. time per variant (hours)	Total time (hours)
Pythia-6.9b	5	70	350
Pythia-1b	5	10	50
Pythia-410m	5	5	25
Pythia-160m	5	1	5
Pythia-70m	5	1	5
Overall time:			435

Table 1: Approximate compute required for the final experiments.

L EXAMPLE FEATURE DASHBOARDS FOR PYTHIA-6.9B

These ‘feature dashboards’ provide the per-feature evidence behind the aggregate analysis: activation patterns, token distribution entropy, and auto-interpretability (‘fuzz’ ROC) scores. We include two randomly sampled features for the control, randomized, and trained variants from Section 3, using SAEs trained on every fourth layer of Pythia-6.9b.

L.1 TRAINED

Feature 10065 (Layer 0) - Trained

Entropy: 0.009 | Fuzz ROC: 0.961

Interpretation: Prefixes or words starting with "Re" often indicating repetition, return, or renewal.

Ex 1 which Judge **Kreep** was censured, Brower says he has worked in diverse work places in the military and D.A.'s office, also working with

Ex 2 Example: In Louros v. **Kreikas**, 367 F. Supp. 2d 572 (S.D.N.Y. 2005), the

Ex 3 the Alhambra's arches. Over the years, **Kreber** has supplied the color separations, while printing services were provided by Century Graphics,

Ex 4 treated equal. What was the Statue of Liberty originally used for? Shadows over **Kregen** Schatten über **Kregen**, 1996; English ebook edition

Ex 5 by Boston attorney Arthur **Kreiger**, who represented AT&T. Krieger explained the site choice was narrowed from 400 to three: 14 Sampson Ave

Feature 10222 (Layer 0) - Trained

Entropy: 0.050 | Fuzz ROC: 0.970

Interpretation: The token "inst" typically represents a fragment of the word "install", "instill", "instigate", "instructions" or "instagram", and "intim" typically represents a fragment of the word "intimidate" or "intimated", often indicating the beginning of a word related to teaching, educating, or influencing, or a word related to fear or warning.

Ex 1 <|endof|> **intim** villa. Dua kamar tidur yang memiliki akses langsung ke kolam renang. Di setiap kamar

Ex 2 the non-Muslim world more and more fold under their legal **intimidation** as a result of our pacifism, self-hatred and complacency.

Ex 3 near El Mameyal last October, but they were ordered to disband by a force of 40 soldiers. The campaign of **intimidation** may have worked

Ex 4 least in part to the attempt by the Railroad Commission of Arkansas to protect Arkansas shippers and build up Arkansas jobbing centers.' In that case it was **intimated**

Ex 5 than half of those against people were assault cases, while nearly 45 per cent were crimes of **intimidation**. 'No person should have to fear being violently attacked

Feature 100186 (Layer 4) - Trained

Entropy: 0.096 | Fuzz ROC: 0.993

Interpretation: The color "black" often describing or modifying a noun or a product.

- Ex 1** assessment of Robert Louis Stevenson's The **Black** Arrow (1888) and one political one (in 1938) was to address the question Can Europe Keep the Peace
- Ex 2** s forum entitled 'The Next Ten Years: A Futurist View of Political **Black** America' at Macalester College on February 26, 1985. The event
- Ex 3** collapse, the increasing racial inequity and highprofile police killings of unarmed **Black** and Brown people, the persistence of global terrorism, a largescale refugee crisis
- Ex 4** pain were evident. On Sunday evenings when CBS covered the war in Vietnam on 60 Minutes. Kent State. Martin Luther King assassinated. The **Black** Panthers. The
- Ex 5** with huge savings. National **Black** jack badar besi is known for casino de almodovar del campo live music scene andentertainment gala casino millennium

Feature 102193 (Layer 4) - Trained

Entropy: 0.233 | Fuzz ROC: 0.841

Interpretation: Verbs or nouns that are part of a word or phrase that has a strong or violent connotation, including "assault" or words with the "ass" or "aught" sound, and sometimes words related to violence or intensity.

- Ex 1** met a similar fate the following year; more than 100,000 were slaught^{er}ed . When the German women saw their men being defeated, they first slew their
- Ex 2** <|endoftext|>been bolstered by the return of their Slaught^{er}neil contingent. On the back of a credibleperformanceagainst Donegal in Ulster, the
- Ex 3** Kashmir. They are largely reared by a tribe of nomadic people called the 'Changpa'. At present, these goats are rarely slaught^{er}ed
- Ex 4** wearing the hat. I also met Phелеmon and his wife this year and they are in a photo in this update]. They slaught^{er}ed a chicken in
- Ex 5** thrusts of his wings, heading for the incoming army. He's going to be slaught^{er}ed as well, Nyx thought. He's

Feature 100186 (Layer 8) - Trained

Entropy: 0.097 | Fuzz ROC: 0.797

Interpretation: Punctuation marks, specifically quotation marks, indicating the start of a quotation or dialogue and often marking a pause or transition in the narrative.

Ex 1 . Asya's spanner was in her hand before she even thought about it. They rushed around the machine to find the source of the noise.■

Ex 2 bring his death.■Nyx■lurched forward, nearly tumbling from his rickety, ragged cot, as ■the edges of his nightmare quickly dissolved from

Ex 3 the corners of his mind.■He sat still, his hands grabbing the wooden bed frame tightly as he tried to catch his breath; tried to control his hammer

Ex 4 breathed a deep sigh as the shaking stopped and the telescope resumed its slow, steady turn.■With a thud, she leapt down onto the workshop floor

Ex 5 whitewashed pine walls before I'm jerked forward.■Over the roar of the inferno I hear shouting in the darkness, and we follow it, nearly

Feature 10092 (Layer 8) - Trained

Entropy: 0.057 | Fuzz ROC: 0.962

Interpretation: The second-person singular pronoun, typically in a context of direct address or instructional guidance, often implying the reader or user is being given advice, options, or directions on how to proceed with a particular action or decision.

Ex 1 fee secure because we guarantee your privacy. Feel free to get exclusive help, expert assistance and free painting quotes because ■you ■are in trusted hands in Bussey

Ex 2 In addition, ■you?ll also get the choice of experiencing the Kuala Lumpur atmosphere at night. ■You will for sure ■have an unforget

Ex 3 of work. Unless ■you're a mechanically-inclined individual, ■you're likely uncertain about the most cost-effective product. Fortunately, ■you

Ex 4 . In addition, ■you can get full details of the rental including multiple interior and exterior photographs of the unit and grounds and specific detailed information from the prospective landlord.

Ex 5 in so many ways! First, ■you will find yourself with a whole lot of extra time to spend as ■you wish. In addition, ■you will see your grades

Feature 100351 (Layer 12) - Trained

Entropy: 0.443 | Fuzz ROC: 0.839

Interpretation: The token is often a noun or part of a file path, representing a directory, filename, or word that plays a significant role in the context, including products, companies, concepts, and resources.

Ex 1 `scripts/xf.script" zipScript="scripts/zf.script" /> </pre> where: *<b>name</b> is any`

Ex 2 `= "scripts/df.script" xmlScript="scripts/xf.script" zipScript="scripts/zf.script" interval="5000" /> </`

Ex 3 `ff48.php 108 . Use of undefined constant catid - assumed 'catid' /var/www/html/huake`

Ex 4 `catid - assumed 'catid' /var/www/html/huakeyun.com/sharevid.cn/#runtime/Cache/`

Ex 5 `html/huakeyun.com/sharevid.cn/#runtime/Cache/Content/b9370d94c960b3ef5`

Feature 100898 (Layer 12) - Trained

Entropy: 0.164 | Fuzz ROC: 0.967

Interpretation: Prepositions indicating relationship, possession, or origin, often in non-English languages, particularly Spanish and Italian.

Ex 1 `ashlheet Tamazight Dictionary: Tamazight - English and English - Tamazight. El libro comprendido como una unidad de ho`

Ex 2 `<|endofxtext|>bas separado del entorno de ... bueno pues quer237;a saber si el alcohol de limpieza(el bosque verde)`

Ex 3 `uit, Victorian Farm film entier youtube. Enfin, j'ai obtenu le lien de confiance! Je viens de m'insc`

Ex 4 `<|endofxtext|>water relationship. Rsum. La prsente tude a comme objectif d'examiner les rpercussions de la scheresse`

Ex 5 `<|endofxtext|>más nada. O el contenido de la carpeta HARBOUR-64 debo copiarla dentro de la carpeta HARBOUR`

Feature 100102 (Layer 16) - Trained

Entropy: 0.414 | Fuzz ROC: 0.957

Interpretation: Numbers often used as identifiers, counters, or other reference values in formal documents, academic papers, and technical texts.

Ex 1 , no damage towing service. Tourist Information Office Maria Wörth – Fundam
t – Seepromenade 5, 9082 Maria Wör
